REPORT ON RATA & COMPLIANCE TESTING

Performed for: MARATHON PETROLEUM COMPANY LP FCCU CHARGE HEATER STACK (SV11-H1) DETROIT REFINERY

> Client Reference No: 4100356132 CleanAir Project No: 12799 Revision 0: September 29, 2015

To the best of our knowledge, the data presented in this report are accurate, complete, error free, legible and representative of the actual emissions during the test program. Clean Air Engineering operates in conformance with the requirements of ASTM D7036-04 Standard Practice for Competence of Air Emission Testing Bodies.

PROJECT OVERVIEW

INTRODUCTION

Marathon Petroleum Company LP (MPC) contracted Clean Air Engineering (CleanAir) to perform emission measurements at the Detroit Refinery for relative accuracy test audit (RATA) and compliance purposes. Additional emission measurements were also made for diagnostic purposes.

All testing was conducted in accordance with the regulations set-forth by the United States Environmental Protection Agency (EPA) and the Michigan Department of Environmental Quality (DEQ). The permit limits are referenced in Michigan Department of Environmental Quality, Air Quality Division Permit to Install No. 63-08D, issued May 12, 2014.

Key Project Participants

Individuals responsible for coordinating and conducting the test program were:

Crystal Davis – MPC Joe Reidy – MPC Thomas Gasloli – DEQ Medel Cendana – CleanAir

Test Program Parameters

The testing was performed at the FCCU Charge Heater Stack (Emission Unit ID No. EU11-FCCUCHARHTR-S1; Stack ID No. SV11-H1) on August 4-5, 2015, and included the following emissions measurements:

- particulate matter (PM), assumed equivalent to filterable particulate matter (FPM) only
- volatile organic compounds (VOCs), assumed equivalent to total hydrocarbons (THC) minus the following constituents:
 - \circ methane (CH₄)
 - ethane (C_2H_6)
- carbon monoxide (CO)
- flue gas composition (e.g. O₂, CO₂, H₂O)
- flue gas flow rate

PROJECT OVERVIEW

Results Summary

Tables 1-2 and 1-3 summarize the results of the test program. A more detailed presentation of the test conditions and results of analysis are shown on pages 2-1 through 2-9.

| Source | | | Average | |
|---------------------|----------------------------------|-----------------|----------|--------------|
| Constituent (units) | Fuel type | Sampling Method | Emission | Permit Limit |
| CCU Heater Stack | | | | |
| PM (lb/MMBtu) | Refinery gas & Disulfide off-gas | USEPA 5 | 0.0027 | N/A |
| VOC (lb/MMBtu) | Refinery gas & Disulfide off-gas | USEPA 18/25A | <5.2E-04 | 0.0055 |
| CO (lb/MMBtu) | Refinery gas & Disulfide off-gas | USEPA 10 | <0.0004 | 0.02 |
| PM (Ib/MMBtu) | Refinery gas | USEPA 5 | 0.0015 | 0.0019 |

Table 1-3: Summary of RATA Results

| <u>Source</u> Constituent (Units) | Reference Method (USEPA) | Applicable Specification | Relative Accuracy ¹ | Specification Limit ² |
|--------------------------------------|-----------------------------|-----------------------------|--------------------------------|----------------------------------|
| FCCU Charge Heater Stack | | | | |
| O ₂ (% dv) | 3A | PS3 | 0.3 | ±1.0% dv |
| CO (lb/MMBtu) | 10 | PS4A ³ | 0.0 | 5% of Standard |

¹ Relative Accuracy is expressed in terms of comparison to the reference method (% RM) or applicable emission standard (% Std.).

² Specification limits obtained from 40 CFR 60, Appendix B, Performance Specifications.

³ For any sources emitting less than 200 ppmv of CO, PS4A applies. The PS4A RA limit is either < 10% of RM, < 5% of Standard, or ± 5 ppmv (abs. average difference plus 2.5 x confidence coefficient).</p>

1-5

PROJECT OVERVIEW

Reference method and facility RATA test run averages which were negative were treated as zero when calculating the relative accuracy.

The facility CEMS results as lb/MMBtu were calculated and provided by MPC along with all other applicable RATA and process data and can be found in Appendix H.

RM CO results from the RATA were used to demonstrate compliance with the permit limit. The final results were expressed as the average of the 11 valid RM RATA runs for CO. The final results were below the permit limit.

CleanAir measured CO drift-corrected concentrations which were negative and consequently below the assumed detection limit of 1% of the instrument calibration span for all test runs. The worst-case concentration results used to calculate mass-based emissions in regards to the emission compliance test is defined as some number "less than" 1% of the calibration span.

VOC Testing - USEPA Methods 25A and 18

VOC testing was performed concurrently with the RATA testing. Nine (9) 21-minute Method 25 test runs for THCs were performed concurrently with three (3) Method 18 bag collections for CH_4 and C_2H_6 , with each Method 18 sample collected over a period of about 63 minutes.

The Method 18 samples on the FCCU Charge Heater were collected as follows:

- Method 18 Run 1: Collected during Method 25A Runs 1, 2 and 3
- Method 18 Run 2: Collected during Method 25A Runs 4, 5 and 6
- Method 18 Run 3: Collected during Method 25A Runs 7, 8 and 9

VOC emission rate is normally equivalent to THC emission rate, minus CH_4 and C_2H_6 emission rate (lb/MMBtu for all constituents). For CH_4 and C_2H_6 , a non-detectable result was obtained for all runs, so no correction was made to the THC results. Therefore, VOC emissions are equivalent to THC emissions. The final results were expressed as the average of three (3) valid runs and were below the permit limit.

PROJECT OVERVIEW

Fuel Analysis & Calculation of Final Results

Testing on August 5, 2015, occurred with the unit firing refinery gas only; MPC provided CleanAir with a refinery gas analysis corresponding to the date of testing. An oxygen-based fuel factor (F_d) for refinery gas was calculated per USEPA Method 19 specifications, from percent volume composition analytical data included in the fuel gas analysis and tabulated heating values for each of the measured constituents. The calculated F_d was used to convert emission results in units of dry volume-based concentration (lb/dscf) to units of pounds per million Btu (lb/MMBtu).

Testing on August 4, 2015, occurred with the unit firing refinery gas and disulfide offgas. When the unit utilizes both of these gases, natural gas must also be added to the fuel stream. MPC provided CleanAir with a gas analysis for refinery gas (sampled August 4, 2015), disulfide off-gas (sampled August 4, 2015), and natural gas (sampled August 13, 2015).

MPC also provided CleanAir with fuel flow rates for all 3 gases for the duration of each test run. The fuel flow rates for refinery gas and disulfide off-gas was corrected by MPC based on a meter correction factor, and the fuel flow rate for natural gas was estimated by MPC.

An F_d for refinery gas and disulfide off-gas was calculated in the same manner as outlined on the previous page. A default F_d for natural gas was utilized and obtained from USEPA Method 19, Table 19-2. Heat input was calculated using the respective F_d and fuel flow rate for each fuel. A combined F_d for each test run was calculated utilizing the fraction of total heat input for each fuel. The calculated combined F_d was used to convert emission results in units of dry volume-based concentration (lb/dscf and ppmdv) to units of lb/MMBtu.

| TB + | | 4.64E-07 | | 0.414 | | 0.00456 |

AVG (average) is the mean value of the runs; N is the number of individual runs.

SD (standard deviation) and RSD (relative standard deviation) are measures of the variability of individual runs.

SE (standard error) and RSE (relative standard error) are measures of the variability of the average of the runs.

P (probability) is the confidence level associated with the two-tailed Student's t-distribution.

TINV (t-value) is the value of the Student's t-distrubution as a function of P (probability) and N-1 (degrees of freedom).

CI (confidence interval) indicates that if the test is conducted again under the same conditions, the average would be expected to fall within the interval (CI- to CI+) about 95% of the time.

TB+ (upper tolerance bound) is the value below which 95% of future runs are expected to fall (assuming testing at the same conditions).

AVG (average) is the mean value of the runs; N is the number of individual runs.

SD (standard deviation) and RSD (relative standard deviation) are measures of the variability of individual runs.

SE (standard error) and RSE (relative standard error) are measures of the variability of the average of the runs.

P (probability) is the confidence level associated with the two-tailed Student's t-distribution.

TINV (t-value) is the value of the Student's t-distrubution as a function of P (probability) and N-1 (degrees of freedom).

CI (confidence interval) indicates that if the test is conducted again under the same conditions, the average would be expected to fall within the interval (CI- to CI+) about 95% of the time.

TB+ (upper tolerance bound) is the value below which 95% of future runs are expected to fall (assuming testing at the same conditions).

Average includes 3 runs.

¹ Moisture data used for ppmwv to ppmdv correction obtained from nearly-concurrent M-5 runs.

For THC, '<' indicates a measured response below the detection limit (assumed to be 1% of the instrument calibration span).

For methane and ethane, '<' indicates a measured response below the analytical detection limit determined by the laboratory. For VOCs, '<' indicates at least one non-detectable fraction was used in the calculations. '<' values for methane and ethane are treated as the entire value of the analytical detection limit.

For all calcuated averages, "<" values are treated as the entire value of the detection limit.
