AIR QUALITY DIVISION

RENEWABLE OPERATING PERMIT REPORT CERTIFICATION

Authorized by 1994 P.A. 451, as amended. Failure to provide this information may result in civil and/or criminal penalties.

Reports submitted pursuant to R 336.1213 (Rule 213), subrules (3)(c) and/or (4)(c), of Michigan's Renewable Operating Permit (ROP) program must be certified by a responsible official. Additional information regarding the reports and documentation listed below must be kept on file for at least 5 years, as specified in Rule 213(3)(b)(li), and be made available to the Department of Environmental Quality, Air Quality Division upon request.

1.0 INTRODUCTION

This section of the report describes the test purpose and provides a brief outline of the test activities and the personnel involved in the test program performed at the Knauf Insulation, LLC (Knauf Insulation) facility in Albion, Michigan.

1.1 Purpose

The purpose of the test program was to determine compliance with emission limits established in Michigan Department of Environmental Quality ROP Permit No. MI-ROP-B7205-2009. The tests were also subject to the requirements of 40 CFR Part 60, Subpart PPP and 40 CFR Part 63, Subpart NNN. Sampling was performed at the Line Nos. 1, 2 & 4 Melter Baghouse Stack (SV-MELT 6, 7 & 9), Resinated Line 1 Collection Stack (SV-SCRUBBER), Resinated Line 1 Curing & Cooling Table Stack (SV-HEAF), Resinated Line 3 Collection, Curing & Cooling Table Stack (SV-EP0023), Resinated Line 3 Melter Baghouse Stack (SV-EP0022) and Non-Resinated Line Nos. 2 & 4 Collection Stack (SV-WETSCRUBBER). The Resinated Line 1 Collection Stack and Resinated Line 1 Curing & Cooling Table Stack were tested under two operating conditions to establish operating ranges for each venturi scrubber. The Resinated Line 3 Collection, Curing and Cooling Table Stack was also tested at two venturi scrubber operational conditions. The two operational conditions are required in 40 CFR Part 63, Subpart NNN. A set of three test runs was conducted at each condition. One condition was set at minimum water flow and differential pressure and the second condition was set at maximum water flow and differential pressure in order to establish minimum and maximum values that will be used to determine compliance after the performance tests. The testing was conducted with all process lines at an operational rate above 8,100 lbs/hr (90% of maximum design).

1.2 Outline of Test Program

Integrity Air Monitoring, Inc. (Integrity Air) performed stationary source sampling on September 29 – October 3, 2014. Table 1 details the sources tested, the pollutants of interest, the United States Environmental Protection Agency (US EPA) Reference Methods used to quantify the pollutants and the run time for each reference method. The sampling included three sampling runs for each target pollutant. The sampling at Resinated Line 1 Collection Stack and Resinated Line 1 Curing & Cooling Table (HEAF) Stack was performed simultaneously during both operational conditions.

| Lines 2 & 4 Non-Resinated Collec | tion Scrubber – 10/0 | 3/14 |
| PM & TOC | 2-hours | 5E |
| Filterable & Condensible PM | 2-hours | 5/202 |

In addition to the sampling performed for the target pollutants, Integrity Air also performed US EPA Reference Methods 1, 2, and 4 to determine the location of the sampling points, the volumetric flow rate and the molecular weight and the moisture content, respectively. Integrity Air followed standard operating procedures (SOP) IAM-001, 002 and 017 as described in Version 1.7 of Integrity Air's Quality Manual.

A Site-Specific Test Plan was submitted to the State of Michigan Department of Environmental Quality (MDEQ) prior to sampling. There were no deviations from the reference methods, SOP's or Integrity Air's Quality Manual during this test project. There were no external environmental conditions such as rain, wind, cold or heat that impacted the integrity of the test results.

1.3 Test Participants

Representatives from the MDEQ were invited to witness the test program. Table 2 is provided to detail the Integrity Air Monitoring test personnel and contact information. The Integrity Air Monitoring, Inc. project manager for this project was J.A."Tony" Blanton. Mr. Blanton's contact information is provided should any testing related questions arise. Table 2 also provides the MDEQ personnel present and the main Knauf Insulation personnel involved in the test proceedings and production issues and their contact information.

2.0 RESULTS

This section presents the sampling results in tabular form. Detailed sampling results and example calculations for the test program can be found in Appendix 1.

2.1 Summary of Results

Tables 3 through 11 present the results from the sampling performed at each source and for each operating condition.

2.2 Discussion

These results are primarily intended to demonstrate compliance with federal and state air quality standards. Additional sampling was performed for compounds outside of the permit requirements and will be used by Knauf Insulation for future emissions inventories and permit modifications.

2.2.1 Production During Tests

Tables 3 through 11 include process operational parameters and production rates. Additional information regarding operational parameters and the hand recorded data sheets can be found in Appendix 5. Information on the free formaldehyde content of the resin is provided in Appendix 6.

3.0 PROCESS DESCRIPTION

This section contains a brief description of the processes and related control equipment.

Knauf Insulation, LLC (Knauf) operates a fiberglass insulation manufacturing plant in Albion, Michigan. Knauf has four fiberglass manufacturing lines, identified as Line 1, Line 2, Line 3 and Line 4. Line 1 and Line 3 are capable of producing resinated wool fiberglass insulation. Line 2 and Line 4 are capable of producing non-resinated wool fiberglass insulation. The wool fiberglass production lines are a continuous process consisting of the following processes:

- Raw materials handling
- Melting and Refining
- Forming and Collection
- Curing and Cooling
- Facing, Sizing, and Packaging

Each process step and its associated controls and emission configuration is described in the following subsections.

3.1 Raw Materials Handling

The glass batching (or raw material handling) operation consists of unloading trucks and rail cars, storing the contents, and blending the various raw materials used to produce glass. Raw materials include silica sand, cullet (broken glass), syenite sand, soda ash, borax and lime. These raw materials are conveyed to storage silos from which they are later weighed and blended in the proper proportions for the particular type of glass to be manufactured. Knauf also recycles cullet and baghouse dust from the process, which is blended into the mixed glass "batch". After blending, the mixed glass "batch" is conveyed to the melting area where it is fed into the melters.

The primary control measure for potential particulate matter emissions for the batch mixing operation is bin vents and the facility building, which acts as a process enclosure to limit airborne particulate matter from being released to the outside ambient air. Storage bins for raw materials and mixed batch are equipped with bin vents (or fabric filters) for control and recovery of materials, which are vented to the in-plant environment.

3.2 Melting and Refining

The next step in the wool fiberglass manufacturing process consists of melting the batch and delivering the molten glass to the fiberization units ("fiberizers") by means of a melter and a forehearth. The batch is electrically melted and formed into glass in a "steel shell" melter. From the melter, the glass flows to a gas fired brick forehearth from which the glass can be divided into several small streams, one for each fiberization unit.

An electrically fired, water cooled, brick lined melting unit is used to melt the batch for each production line. Particulate matter emissions occur from the loading of batch mix into the melters. Potential particulate matter emissions are collected from above the melters by two Rayjet dust collectors on Lines 1, 2 and 4 and is vertically discharged from the combined melter baghouse stack, SV-MELT 6,7,9, to the outside ambient air. On Line 3, a Mactiflo cartridge baghouse is used and vertically discharges from the baghouse stack, SV-EP0022, to the outside ambient air.

Molten glass flows from the melters to dedicated natural gas fired forehearths. The purpose of the forehearth is to split the molten glass flow into several streams, and present a consistent glass flow (or pull rate) to each fiber-forming unit. Potential regulated air pollutant emissions from the Lines 1, 2 and 4 forehearths are vented internally to the ambient air. Potential regulated air pollutant emissions from the Line 3 forehearth are combined with the exhaust system serving the forming, conditioning and collection processes.

3.3 Forming and Collection

Fiber forming units, or fiberizers, are positioned below orifices in the Forehearth to receive the molten glass stream, and "spin" it into glass fibers. The fiberizers use centrifugal force, natural gas heat, and compressed air blast to form the fibers.

A mixture of binder, dedusting agent and overspray (pit) water are applied to the fibers just below the fiberizers for the resinated line. For non-resinated product production, a silicone copolymer is sprayed onto the fibers.

Conditioned fiber from the fiberizers is pulled down onto the collection chain in the vacuum chamber, by fans located downstream of the collection plenum called suction fans. The collection plenum on the resinated lines is a box where the vacuum chamber exhaust is impinged with a water spray to control buildup of fiber on the plenums. The exiting exhaust is then accelerated through a transition duct to venturi scrubbers where it is subjected to additional water sprays to control particulates. The suction

fans discharge the scrubbed gas stream vertically through the collection exhaust stack SV-SCRUBBER for Line 1 and SV-EP0023 for Line 3 to the outside air.

On the non-resinated Lines 2 and 4, the collection exhaust air passes through venturi scrubbers and is then discharged vertically through the collection exhaust stack SV-WETSCRUBBER to the outside air.

3.4 Curing and Cooling

For resinated production, the collected fibers, coated with binder and dedusting agent, are conveyed to a natural gas-fired, recirculation air oven, where the fiberglass blanket is sized to thickness and the binder is cured by means of the recirculating heated air. A cooling section is provided downstream of the curing oven, where ambient plant air is drawn through the cured fiberglass blanket.

Potential regulated air pollutant emissions from the Line 1 curing section of the wool fiberglass manufacturing line are collected and controlled with a High Efficiency Air Filter (HEAF). Potential regulated air pollutant emissions from the Line 1 cooling section of the wool fiberglass manufacturing line are collected and controlled with a venturi scrubber. Both of the scrubbed gas streams vertically discharge through the combined curing and cooling table exhaust stack SV-HEAF to the outside air.

Potential regulated air pollutant emissions from the Line 3 curing and cooling sections of the wool fiberglass manufacturing line are collected and controlled with venturi scrubbers, and the scrubbed gas stream vertically discharged through the collection, curing and cooling table exhaust stack SV-EP0023 to the outside air.

No curing is required for non-resinated fiberglass.

3.5 Facing, Sizing and Packaging

The resinated product is next conveyed to the slitting operation where batts and rolls are sized for length and width according to customer demand. If applicable to the product being manufactured, a vapor barrier facing paper is applied.

Wool fiberglass insulation may either be produced with or without the application of the facing paper. When facing is applied, a hot roll facing applicator is used to electrically heat the facing paper or hot melt glue is used to adhere the facing to insulation. In the sizing operation, wool fiberglass insulation is slit with slitter saws to width, and then chopped to length with choppers. The sized insulation is then folded and packed into batts, or rolled and over wrapped. Trim and scrap are fed into the dicers, and the blowing wool bagger or scrap materials may be fed back into the wool fiberglass blanket. The finished product is packaged, stored and shipped.

Non-resinated fiberglass is conveyed from the forming chamber to the dicers where dedusting oil is applied. The diced product is then placed into bags, stored in the warehouse and shipped.

Potential particulate matter emissions from sizing and packaging area equipment are collected and controlled with wet impingement air tumbler, tube sock filters and/or screen room filters. The exhaust from these devices exhausts to the inside plant air.

3.6 Demonstration of Operating Rate

Copies of the glass pull rate and process information recorded during sampling periods are included in Appendix 5.

4.0 SAMPLING METHODS

This section describes the sampling strategy, sampling and analytical methods, and quality assurance/quality control procedures implemented during this project.

4.1 Sampling Strategy

The sampling and analytical procedures used during this test program were those established by the US EPA and MDEQ. A Sampling Protocol was submitted to MDEQ prior to the sampling and was adhered to through out the test program. Tests were conducted during specific operating conditions. There were no unusual operating conditions noted during the sampling.

4.2 Sampling and Analytical Procedures

The following table provides the US EPA methods used in this sampling program.

| Table 12 – Sampling and Analytical Procedures | | | | | |
|---|---|--|--|--|--|
| Reference Method | Parameter | | | | |
| 1 | Location of Sampling Points | | | | |
| 2 | Volumetric Flow and Molecular Weight | | | | |
| 4 | Moisture Content | | | | |
| 5 | Particulate Matter | | | | |
| 5E | Particulate Matter & TOC | | | | |
| 202 | Condensable Particulate Matter | | | | |
| 318/320 | Formaldehyde, Phenol, Methanol, Formic Acid & Ammonia | | | | |
| 306 | Total Chromium | | | | |

A sampling and analysis synopsis for each of these methods is discussed briefly in the following subsections. These test methods are available in the Code of Federal Regulations Volume 40, Part 60 or by request from Integrity.

4.2.1 Sampling Ports, Traverse Points and Cyclonic Flow

The sampling locations were prepared according to the criteria in Method 1. The duct diameters upstream and downstream from the sampling ports were measured and documented prior to sampling. The number of traverse points was chosen with respect to sampling port location. The amount of cyclonic flow was determined according to the criteria detailed in Method 1.

4.2.2 Stack Gas Velocity and Volumetric Flow Rate Determination

Method 2 is used to determine the average gas velocity in a stack using the average temperature and average velocity head. The temperature is measured with a calibrated thermocouple and the velocity determined with a Type S (Stausscheibe) pitot tube. This method is further used to calculate volumetric flow rate.

Measurements of velocity head and temperature at the inlet and exhaust test locations were performed at the traverse points specified by Method 1. A differential pressure gauge scaled for the range of Δp values encountered during the traverse was used. An inclined manometer (oil type) scaled 0.00 - 0.25 or 0 - 10 inches of water, was used at the outlet test locations.

Each apparatus was set-up according to manufacturer and reference method recommendations. Pre-test and post-test leak checks were conducted. The atmospheric and static pressure of each duct was also determined for each set of velocity head readings. The volumetric flow rate calculations used were those specified in Method 2.

4.2.3 Dry Molecular Weight Determination

Method 3 is applicable for determining carbon dioxide and oxygen concentrations and dry molecular weight of a sample from a gas stream of a fossil-fuel combustion process. This method may also be applicable to other processes where it has been determined that compounds other than carbon dioxide, oxygen, carbon monoxide, and nitrogen are not present in concentrations sufficient to affect the results.

Since the sources were emitting essentially air, a dry molecular weight of 29.0 was used according to Method 2, Section 8.6.

4.2.4 Moisture Determination

Method 4 was used to determine the stack gas moisture content. The moisture content is used to correct the concentration or mass emission rate to a dry basis. The moisture content at each test location was determined in conjunction with Reference Method 5. This procedure is discussed in Section 4.2.5.

4.2.5 Particulate Matter Sampling and Analysis

Sampling and analysis for total particulate matter (condensable and non-condensable) was performed according to US EPA Methods 5 and 202. The principal components of the sampling system were sequentially:

- A stainless steel sample nozzle and borosilicate glass probe liner;
- A heated (248°F ±25°F) probe and filter assembly with tared glass fiber filter;
- A Method 23-type condenser kept below 85 degrees F using recirculating water;
- A dry impinger section consisting of a dropout impinger followed by a modified Greensburg-Smith impinger;
- A glass filter holder (with thermocouple) containing an untared Teflon membrane filter and Teflon frit;
- A cold section consisting of two sequential impingers. The first impingers contained 100 ml of deionized water followed by a final impinger containing 200 grams of silica gel; and
- A metering system capable of maintaining an isokinetic sampling rate and accurately determining the sample volume according to those specifications in APTD-0581.

Sample recovery began immediately following each run. The filter was removed from the glass filter support and sealed in a petri dish. The nozzle, probe liner, and front half of the filter assembly were brushed and rinsed with acetone into a glass storage container which was sealed and the liquid level was marked. The sample containers were transported to Integrity's Air Quality Laboratory in Huntersville, North Carolina.

The non-condensable particulate matter analyses began by transferring the acetone samples to tared beakers. These samples were taken to dryness, placed in an oven at 104°C for one hour and then placed in a desiccator along with the filters for an initial drying period of 24 hours. The non-condensable particulate mass was determined gravimetrically. The tare weights of the filters and beakers were subtracted from the final weights to determine the net non-condensable particulate weight. An aliquot of the reagent grade acetone was analyzed to determine the blank correction factor. The acetone rinse (corrected for the blank) was added to the filter catch to obtain the non-condensable particulate weight.

The condensable portion of the sampling system was purged with filtered ultra-high purity nitrogen for one hour and then measured to the nearest milliliter. This moisture collected in the first two impingers (prior to the Teflon membrane filter) was placed in a high-density polyethylene (HDPE) container (container 1) along with the water rinses of the condenser, impingers, connecting glassware and front-half of the filter holder. The same components were then rinsed with acetone and twice rinsed with hexane. The solvent rinses were combined in one glass container (container 2). The Teflon membrane filter was placed in a petri dish. All sample containers were sealed and the liquid level was marked. The moisture collected by the impinger following the filter holder and the silica gel was determined to the nearest 0.1 gram and discarded.

A field train blank and reagent blanks (water, acetone and hexane) were submitted along with the samples and chain of custody documentation. The samples were analyzed in-house by Integrity Air. Documentation of the laboratory analyses and chain of custody can be found in Appendix 3.

4.2.6 Particulate Matter and TOC Sampling and Analysis

Sampling and analysis for particulate matter and total organic carbon (TOC) was performed according to US EPA Method 5E. The principal components of the Method 5E sampling system were sequentially:

- A borosilicate glass sample nozzle and probe liner;
- A heated (248°F ±25°F) probe and filter assembly with tared glass fiber filter;
- An impinger train consisting of four sequential impingers. The impingers contained 100 ml each of 0.1N NaOH in the first two impingers followed by an empty impinger and a final impinger containing 200 grams of silica gel.
- A metering system capable of maintaining an isokinetic sampling rate and accurately determining the sample volume according to those specifications in APTD-0581.

Method 5E sample recovery began immediately following each run. The filter was removed from the glass filter support and sealed in a petri dish. The liquid in the first three impingers was measured to the nearest milliliter. The moisture collected by the silica gel in the fourth impinger was determined to the nearest 0.1 gram. The collected condensate measurements were recorded on the corresponding field data sheet and placed in a labeled sample jar. The impingers and connecting glassware were rinsed three times with 0.1N NaOH and placed into the same container as the condensate catch.

The nozzle, probe liner, and front half of the filter assembly were first rinsed with deionized water into a glass storage container which was sealed and the liquid level was marked. The nozzle, probe liner, and front half of the filter assembly were then brushed and rinsed with acetone. The rinses were collected into a separate glass storage container which was sealed and the liquid level was marked. The sample containers were transported to Integrity's Air Quality Laboratory in Huntersville, North Carolina.

The particulate matter analyses began by transferring the acetone and deionized water rinse samples to tared beakers. These samples were taken to dryness at 68 ° F +/- 10° and ambient pressure, and then placed in a desiccator along with the filters for an initial drying period of 24 hours. The non-condensable particulate mass was determined gravimetrically. The tare weights of the filters and beakers were subtracted from the final weights to determine the net non-condensable particulate weight. An aliquot of the reagent grade

acetone and deionized water were analyzed to determine the blank correction factor. The acetone and deionized water rinses (corrected for the blanks) were added to the filter catch to obtain the noncondensable particulate weight. Integrity personnel performed the particulate matter and method blank analyses in-house. Analysis for total organic compound (TOC) was performed by Element One. A detailed analysis and analytical description, appropriate documentation of the laboratory analyses, and chain of custody can be found in Appendix 3.

4.2.7 Total Chromium Sampling and Analysis

Testing for total chromium was performed according to US EPA Method 306. Gaseous and particulate pollutants were withdrawn isokinetically from the emission source and collected in a multicomponent sampling train.

The principal components of the sampling system were sequentially:

- A borosilicate glass nozzle and probe liner;
- An impinger train consisting of four sequential impingers. The first two impingers contained 100 ml each of 0.1N sodium hydroxide followed by an empty impinger and a final impinger containing 200 grams of silica gel; and
- A metering system capable of maintaining an isokinetic sampling rate and accurately determining the sample volume according to those specifications in APTD-0581.

Sample recovery began by measuring the liquid in the first three impingers to the nearest milliliter. The ph of the absorbing solution was checked and verified to be greater than 8.5. The moisture collected by the silica gel in the fourth impinger was determined to the nearest 0.1 gram. All collected condensate measurements were recorded on corresponding field data sheets. The nozzle, probe impingers and connecting glassware was rinsed with approximately 200 ml of 0.1N NaOH. The impinger contents and rinses were transferred to a 500 ml high density polyethylene storage container. The container was then sealed and the liquid level was marked. The sample containers were shipped with chain of custody documentation to Element One in Wilmington, North Carolina for total chromium analysis. A 0.1N sodium hydroxide blank was included for analysis. The samples were analyzed using inductively coupled plasma emission spectrometry (ICP) for total chrome and Ion Chromatograph (IC) equipped with a post-column reactor. The laboratory report is included in Appendix 3.

4.2.8 Extractive Fourier Transform Infrared Spectroscopy

Infrared absorption spectroscopy was performed by directing an infrared beam to pass through a sample to a detector. The frequency-dependent infrared absorbance of the sample was measured by comparing this detector signal to a signal obtained without a sample in the beam path.

Most molecules absorb infrared radiation and the absorbance occurs in a specific and reproducible pattern. The infrared spectrum measures fundamental molecular properties such as bond stretching and a compound can then be identified from its infrared spectrum. Within constraints, there is a linear relationship between infrared absorption and compound concentration. When the frequency dependent absorptivity is known (measured), it can be used to quantify compound concentration in a sample mixture. Absorptivity is measured by preparing, in the laboratory, standard samples of compounds at known concentrations and measuring the FTIR "reference spectra" of these standard samples. These "reference spectra" are then used in sample analysis. Compounds are detected by matching sample absorbance bands with bands in reference spectra, and then concentrations are measured by comparing sample band intensities with reference band intensities.

The gas sample was extracted from the source through a heated probe and filter assembly containing a glass fiber filter. The sample was pulled through a heated Teflon sample line to the FTIR using a sample pump attached to the exit of the sample cell. The probe, filter, sample line and gas cell temperatures were maintained at approximately 265°F during testing.

The sample analysis was performed using a MIDAC I-2000 spectrometer equipped with a heated fixed path cell system. One cell was 10 meters and the other cell was 10.0 cm. The detectors were liquid cooled MCT, and the nominal spectral resolution was one half wave number (0.5 cm⁻¹). The path length was determined according to EPA Method 320 by using a certified ethylene cylinder (100 ppm). The path length was determined at the beginning and end of the test day as well as before and after each sampling run. Enthalpy personnel determined dilution factors and calculated target values with mass flow controllers and/or primary standard bubble meters. Detailed information regarding the FTIR analysis can be found electronically on compact disk (Provided in front cover) or by request from Integrity.

4.2.9 Sampling Ports and Points

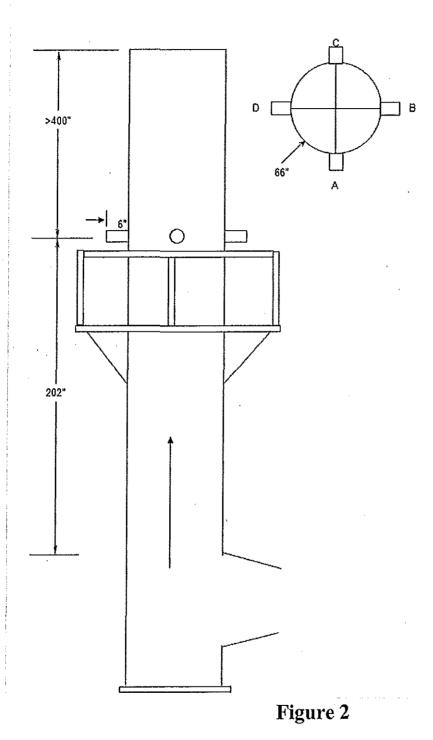

The dimensions of the sampling locations and the location of the sampling ports are detailed in Figures 1 - 6. The drawings provided are not to scale.

4.3 Quality Assurance and Quality Control

Integrity Air Monitoring, Inc. has established quality assurance and quality control (QA/QC) guidelines to ensure the highest quality sampling and analytical data from source tests. As stated in our Quality Manual, Integrity Air carries out source testing activities to comply with the requirements of ASTM D7036-04 for local, state and federal laws and regulations.

Data quality objectives were maintained throughout this project. The following table provides the QA activities followed during this sampling project and the results.

| Table 13 – Project QA Activities and Results | | | | | |
|--|---------------------------------------|----------------|--|--|--|
| Parameter | Criteria | Within Limits? | | | |
| Moisture Train Leak Check | < 0.02 cfm | yes | | | |
| Pitot Tube Leak Check | < 0.1 in. H ₂ O in 15 sec. | yes | | | |
| Console Calibration | γ +/- 0.02 | yes | | | |
| Thermocouples | +/- 2% of ref. temp. | yes | | | |
| Acetone Blank | Conc. < 0.001 | yes | | | |

Quality control procedures for the isokinetic pollutant sampling methods have included the analysis of reagent and field blanks. Method 320 Quality Assurance procedures can be found in the sampling and analysis discussion of the laboratory report and can be found in Appendix 3.

Field data and final laboratory results were independently audited and reviewed for verification of data. The Emission Test Report is audited for completeness and reasonableness of data. The report requires the signature of the project manager and Vice President or President before release to the client. Data and final reports are archived in a secured area for a minimum period of three years.

Integrity's field and laboratory test equipment has been maintained and calibrated in accordance with quality assurance procedures established by the US EPA in the Quality Assurance Handbook for Air Pollution Measurement Systems: Volume III. Equipment calibrations including pre-test and post-test calibration data are presented in Appendix 4.

5.0 APPENDICES

The appendices contain detailed support documentation that encompasses the relevant aspects of the emission test program. This data serves as the foundation for the test report. The emission test report presents a summary of the information gathered during the sampling activities. The following appendices have been provided to facilitate the review of the test report:

Appendix 1 – Detailed Summary of Results and Example Calculations

Appendix 2 – Field Data Sheets

Appendix 3 – Laboratory Data and FTIR Data

Appendix 4 - Calibration Data and Protocol Gas Certificates of Analysis

Appendix 5 – Facility Production Documentation

Appendix 6 - Free-Formaldehyde Content Determination of the Resin
